IceA gene

PCR technique

Background and Aims: *Helicobacter pylori* (*H. pylori*) is a gram-negative, microaerophilic, spiral-shaped flagellated bacterium that is urease, catalase and oxidase positive. One of its pathogenicity factors is the iceA gene. *H. pylori* has recently been recognized as a genetic indicator for the development and evolution of duodenal ulcer disease in the East. This study aimed to determine the presence of this bacterium in gingival plaques in non-endocrine patients in Bojnourd city, and the polymerase chain reaction technique examined the percentage of iceA gene.

Materials and Methods: A total of 100 samples of dental plaque were taken and transferred to a tube that has been physiologically placed. After DNA extraction, primer design was performed, and then the polymerase chain reaction was performed for the whole sample.

Results: Of 100 samples examined in this study, two samples of *H. pylori* were positive (2%), and the frequency of the iceA gene of two samples was positive (100%).

Conclusions: In the Bojnourd city, the frequency of iceA gene in people is high, and the frequency of *H. pylori* in tooth plaques is low. Also, iceA gene can be considered as an indicator for predicting the contamination and risk of *H. pylori* infection in the region. To confirm the results, more molecular studies are required in other populations.

Introduction

Helicobacter pylori (*H. pylori*) is a microaerophilic, gram-negative bacterium that is recognized to be one of the leading causes of gastroduodenal ulcers, gastritis, and gastric cancer [1, 2]. Previous studies about the presence of this bacterium in various specimens of the oral cavity such as dental plaque and saliva revealed that the oral cavity could be a considerable reservoir for *H. pylori* or as a potential route of transmission to other origins of body. The oral cavity can be the second origin of the homing of *H. pylori* that may result in recurrent gastric infection [3]. The reported prevalence of *H. pylori* infection in Asia is 11% to 90%, Africa is 48% to 90%, Central America is 51% to 90%, North America is 7% to 30%, and South America is 54% to 90%, and Europe is observed from 1.2% to 70.7% [4].

Epidemiologic studies conducted in Iran have reported the prevalence of *H. pylori* in the range of 82-92% [5, 6]. Since this bacterium is microaerophilic and requires special conditions for colonization, oral cavity, dental plaque, and periodontal plaques can be significant places for the storage of this bacterium [7]. Despite the impact of multiple genes on the virulence of bacteria, extensive studies could not specify a definitive relationship between the clinical consequences of an infection and a particular gene. In any case, there is a belief among researchers that virulence strains are more likely to cause gastrointestinal diseases, especially gastric ulcers [8-10]. The most critical pathogenicity factors of *H. pylori* include urease, flagellum, adhesion, cagA, vacA, and pathogenicity island (cagPAI) [11].

IceA gene and *H. pylori* have recently been recognized as a genetic indicator for the development of duodenal ulcer disease in the East [12]. Peek and colleagues introduced the gene. *AceA* has two *iceA1*, *iceA2* alleles. The *iceA1* allele codes for the homolog of the *nlaIII*R endonuclease enzyme in *N. lactamica*, and *iceA2* codes the protein with 59 amino acids and does not depend on *iceA1*. The role of *iceA1* gene in human infection has not been determined yet [13-15]. The expression of one of these two depends on the prevalence of the disease and the type of disease. Studies have shown that the *iceA1* allele is linked to a peptic ulcer in the Netherlands and the United States but not in countries such as Japan, Korea, and Colombia [12, 15]. Finally, this study aimed to find out the presence of this bacterium in dental plaque in subjects without symptoms. Therefore, due to the high prevalence of gastrointestinal disorders such as non-ulcers and wounded indigestion, the probability of the bacteria storage in the oral cavity and the percentage of *iceA* gene is evaluated.

Materials and Methods

This study was conducted during 2 years at the Genetics Laboratory of Sari Islamic Azad University. One hundred samples of plaque were taken from Bojnourd city. As a dental plaque was drawn with sterilized swabs, it was pulled into sterilized physiology serum. At the end of each day, the samples were transferred to -70 °C until the DNA could be extracted. Then, by using the

phenol-chloroform protocol, DNA was extracted and subjected to spectrophotometry for quantification. DNA extracts were used to perform the polymerase chain reaction (PCR) technique to detect *H. pylori* by primer sets C97-20 [5'-GGCTATGACGGGTATCCGGC3']; positions [260-279] and H3A-20 [5'-GCCGTGCAGCACCTGTTTTTC-3']; anneals to positions 1007 to 1026 of *H. pylori* 16S rRNA that amplify a fragment with the size of 746 bp and also iceA gene representing *H. pylori* strains by F- ATTACTGACGCTGATTGTGC and R- CTGGAGAGACTAAGCCCTCC primers that can amplify a DNA fragment with the size of 250 bp. We used the *H.pylori* positive sample as the positive control. Eppendorf thermocycler was used for DNA amplification (Roche Co., Germany). Amplification for 16s rRNA was performed in a final volume of 25 µl containing 1 µl of MgCl₂, 0.3 µl of dNTP, 0.3 µl of each primer, 0.2 µl of Taq polymerase, 2.5 µl PCR buffer, 1.5 µl of template DNA and 18.9 µl double-distilled water. DNA amplification for iceA gene was performed in a final volume of 25 µl containing 1 µl of MgCl₂, 0.3 µl of dNTP, 0.4 µl of each primer, 0.2 µl of Taq polymerase, 2.5 µl PCR buffer, 1.5 µl of template DNA and 18.7 µl double distilled water. The amplification for

16s rRNA was performed with an initial denaturation at 94°C for 4 min, followed by 30 cycles of denaturation at 94°C for 60 s, annealing at 57°C for 45 s and extension at 72°C for 60 s with a final extension at 72°C for 10 min. The amplification for iceA gene was performed with an initial denaturation at 95°C for 4 min, followed by 30 cycles of denaturation at 95°C for 60 s, annealing at 56°C for 45 s and extension at 72°C for 60 s with a final extension at 72°C for 10 min. The PCR products were separated on 1% (w/v) agarose gel with 0.5 mg/ml of loading dye and were analyzed by gel electrophoresis. This study was approved by the Ethics Committee of Islamic Azad University, Sari, Iran.

Statistical analysis

Statistical Package for the Social Sciences software (SPSS Inc No. 22) was used for data analysis.

Result

In this study, 98 samples of tooth plaque in Bojnourd city were taken, 2% of them were positive for *H. pylori* (Table 1), and both positive *H. pylori* were positive for iceA gene. Fig. 1. shows PCR amplification products of 16S rRNA gene of *H. pylori*. PCR amplification products of iceA gene of *H. pylori* is presented in Fig. 2.

Sample	Frequency	Frequency (%)	Cumulative frequency (%)
Positive	2	2	2
Negative	98	98	98
Total	100	100	100

Discussion

H. pylori infection is one of the important and common gastric infections all around the world. Recently, these microorganisms have been detected in dental plaques, where the prevalence of these bacteria was supposed to be very low. The presence of bacteria appears to be different in various sites within the oral cavity [16]. The present study identified DNA from *H. pylori* in 2% of clinical dental plaque specimens. Indeed, *H. pylori* infection is affected by public health and low level of economic welfare, so that the prevalence of *H. pylori* in Iran and Brazil is higher than 80% [17,18]. Besides, 72% of patients with the gastric infection have *H. pylori* in their dental plaque in Brazil. Even though this result was in contrast with our result due to having a 2% presence of *H. pylori*, the amount of dental

plaque in the oral cavity has been shown by some researchers to have a direct influence on the rate of *H. pylori* detection in study samples. This implies that improving oral hygiene by regular tooth brushing would improve the oral hygiene status and result in clearance of the bacterium from the mouth. The present investigation found no significant relationship between the frequency of brushing and the presence of *H. pylori* in the understudied dental plaque samples. Nearly 2% of the individuals were positive for the bacterium in their dental plaque samples. Assumpcao et al. (2010) conducted a study called *H. pylori* in the teeth and stomach plaque of northern Brazilian patients. In this study, a cavity plasticized sample and a gastric biopsy specimen were used for histological examination, rapid urease

test, and PCR to detect the presence of *cagA* and *vacA* gene. The results of this study indicated that the detection of *H. pylori* from tooth plaque and gastric biopsy specimens was done mostly by PCR in comparison with the histological examination and urease test. The DNA of *H. pylori* was observed in 96% of the gastric mucosal specimen and 72% of the dental plaque samples. Sixty-three samples (89%) of 71 plaque duplicates that were positive in *H. pylori* have *vacA* and *cagA* genes [19]. In 2008, Shirvani et al. conducted a study on *H. pylori* strains isolated from people with gastroduodenal diseases in Babol city.

Among 50 patients with gastroduodenal gastric biopsy, *CagA* and *iceA* (*iceA2* and *iceA1* alleles) were examined for the presence of these genes. After cultivating and extracting DNA using specific primers for *CagA*, *iceA*, (*iceA2* and *iceA1*) genes, PCR was tested. The results of this study showed that the prevalence of *CagA* was higher in *H. pylori* strains, and the *iceA* allele was also recognized as the dominant allele in this region [20]. In the present study, two positive *iceA* samples were not included in

any of the *iceA2* and *iceA1* alleles that appear to be new alleles of this gene. In this study, the gene of *iceA* was investigated, just like the research. According to previous studies, 100 samples were collected, and 100 samples of these bacteria have been detected in 2% of the samples. Besides, both of the *H. pylori* had an *Ice A* gene, which means 100% of *H. pylori* isolated from the dental plaques were positive for *iceA* gene.

Conclusion

Although the frequency of bacterial detection in dental plaque samples was low, the presence of *iceA* gene in all *Helicobacter* samples was positive. However, due to the high genetic diversity among *H. pylori* strains in different societies, further research on the role of this gene in the development of digestive diseases seems necessary.
